## Optical Density, Light Speed, and the Index of Refraction Lesson Notes

## Learning Outcomes

- How are the optical density of a material, the index of refraction of a material, and the speed of light in the material related?

## REVIEW: Refraction at a Boundary

When a light wave crosses the boundary between two transparent materials, ...

- the speed changes
- the wavelength changes
- the direction changes

The change in direction of a light wave is known as refraction.

How can one predict whether the speed will increase or decrease when crossing the boundary?

## Light Propagation Through a Medium

- Light waves are created by a vibrating charge, resulting in a rapidly fluctuating electric and magnetic field (an EM wave). Image Source: https://commons.wikimedia.org/ wiki/File:Electromagneticwave3Dfromside.gif
- An EM wave travel through empty space at $3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}$, a value known as c .
- It's passage through a transparent material requires the absorption and re-emission of the electromagnetic energy.

- While the particle-to-particle speed is c, the absorptions and re-emissions results in a time delay and the overall speed at which light travels through a material is less than c .

## Optical Density and Light Speed

- Every material has its own unique optical density.
- The optical density describes the general sluggishness of the atoms in absorbing, maintaining, and re-emitting the EM energy as light passes through it.
- The more optically dense that a material is, the slower that light will travel through that material.

| Air | Water | Glass |
| :---: | :---: | :---: |
| Least |  | Diamond |
| Dense |  | Most |
| Fastest light |  | Dense |
| speed |  | Slowest light |
|  | speed |  |

## The Index of Refraction

The index of refraction ( $\mathbf{n}$ ) describes how many times slower light travels in a material relative to its speed in a vacuum.

$$
\mathbf{n}=\frac{\mathbf{c}}{\mathbf{v}} \quad \begin{aligned}
& \mathbf{c}=\text { speed of light in vacuum }\left(3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}\right) \\
& \mathbf{v}=\text { speed of light in a material }
\end{aligned}
$$

Light travels slowest in materials with the highest index of refraction values.

| Material | n | $\mathrm{v}(\mathrm{m} / \mathrm{s})$ |
| :---: | :---: | :---: |
| Air | 1.00 | $3.00 \times 10^{8}$ |
| Water | 1.33 | $2.25 \times 10^{8}$ |
|  | 1.52 | $1.97 \times 10^{8}$ |
|  | 2.42 | $1.24 \times 10^{8}$ |

## Optical Density, n, and Light Speed

- As the optical density increases, the speed of light decreases.
- As the n value increases, the speed of light decreases.
- Most dense materials $\Rightarrow$ Largest $n$ values $\Rightarrow$ Slowest light speeds
- Least dense materials $\Rightarrow$ Smallest $n$ values $\Rightarrow$ Fastest light speeds

The direction that light refracts and the amount that it refracts at a boundary is dependent upon the relative density, $n$ values, and light speed of the two materials.
